Differential Equations HW #3

Ozaner Hansha

October 24, 2019

Problem 1

Problem: Find the general solution to the following system:

$$\begin{cases} \frac{dx}{dt} = 2x\\ \frac{dy}{dt} = 4y - x^2 \end{cases}$$

Solution: This is a partially decoupled system, thus we can solve for x first. Being separable, it is clear that the general solution to x is:

$$x = k_1 e^{2t}$$

Now we plug in our general solution for x into the other ODE and solve the resulting linear ODE for y.

$$\frac{dy}{dt} = 4y - k_1^2 e^{4t}$$

First we find the general solution to the homogenous equation y' = 4y. Like before, it is separable and so the general solution is:

$$y_h = k_2 e^{4t}$$

Via the method of undetermined coefficients, we know that a particular solution y_p to the LDE is of the form:

$$y_p = \alpha t e^{4t}$$

Plugging this into the ODE we find:

$$\frac{dy_p}{dt} = 4y_p - x^2$$

$$4\alpha t e^{4t} + \alpha e^{4t} = 4\alpha t e^{4t} - k_1^2 e^{4t}$$

$$\alpha e^{4t} = -k_1^2 e^{4t}$$

$$\alpha = -k_1^2$$

And so our general solution to y is given by:

$$y = y_h + y_p = k_2 e^{4t} - k_1^2 t e^{4t}$$

Putting it together, our general solution to the system of ODEs is:

$$\begin{cases} x = k_1 e^{2t} \\ y = k_2 e^{4t} - k_1^2 t e^{4t} \end{cases}$$

For arbitrary constants $k_1, k_2 \in \mathbb{R}$.

Problem 2

Problem: Rewrite the following system of ODEs in matrix form:

$$\begin{cases} \frac{dp}{dt} = 3p - 2q - 7r \\ \frac{dq}{dt} = -2p + 6r \\ \frac{dr}{dt} = 7q + 2r \end{cases}$$

Solution: Defining the following variables:

$$\mathbf{p}(t) = \begin{bmatrix} p(t) \\ q(t) \\ r(t) \end{bmatrix} \qquad \mathbf{A} = \begin{bmatrix} 3 & -2 & -7 \\ -2 & 0 & 6 \\ 0 & 7 & 2 \end{bmatrix}$$

We can express the given system, supressing the argument (t), as the following matrix ODE:

$$\frac{d\mathbf{p}}{dt} = \mathbf{A}\mathbf{p} = \begin{bmatrix} 3 & -2 & -7 \\ -2 & 0 & 6 \\ 0 & 7 & 2 \end{bmatrix} \begin{bmatrix} p \\ q \\ r \end{bmatrix}$$

Problem 3

Problem: Consider the following system of equations:

$$\begin{cases} \frac{dx}{dt} = f(x,y) = -3y(1+x^2+y^2) \\ \frac{dy}{dt} = g(x,y) = 2x(1+2x^2+2y^2) \end{cases}$$

- a) Show that $y_1(t) = (\cos 6t, \sin 6t)$ is a solution of this system.
- **b)** Show that if $\mathbf{y}_2(t) = (x_2(t), y_2(t))$ is another solution with $\mathbf{y}_2(1) = (0.5, 0.5)$, then $x_2(t)^2 + y_2(t)^2 < 1$ for all t.

Solution: For a) we simply plug in the solution into the both equations of the system to verify it:

$$\frac{dx}{dt} = -3y(1+x^2+y^2)
-6\sin 6t = -3\sin 6t(1+\cos^2 6t + \sin^2 6t)
= -3\sin 6t(1+1)$$
 (trig. identity)
= -6 \sin 6t

$$\frac{dy}{dt} = 2x(1 + 2x^2 + 2y^2)$$

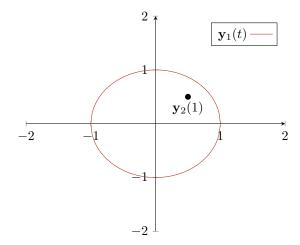

$$6\cos 6t = 2\cos 6t(1 + 2\cos^2 6t + 2\sin^2 6t)$$

$$= 2\sin 6t(1 + 2)$$

$$= 6\sin 6t$$
(trig. identity)

To show **b)** let us first establish the uniqueness of solutions to this system. This is guaranteed by the Picard-Lindelöf theorem as long as $\frac{d(f,g)}{d(x,y)}$ exists and is continuous over some open set. This is trivial, as both f and g are polynomials over x and y and so are continuously differentiable functions with respect to x and y.

Now let us graph the initial point on the xy phase plane, along with the solution from part a):

Due to uniqueness, and this being an autonomous system, no two distinct solutions can cross each other on the phase plane. As a result, whatever the solution \mathbf{y}_2 looks like, simply because it contains a single point in the interior of \mathbf{y}_1 , it will never be able to cross over to its exterior.

Note that the curve \mathbf{y}_1 traces on the phase plane is a unit circle. This means that:

$$(\forall t \in \mathbb{R}) \|\mathbf{y}_1(t)\| = 1$$

And since the curve \mathbf{y}_2 is trapped in the interior of \mathbf{y}_1 , we have for all $t \in \mathbb{R}$:

$$\|\mathbf{y}_{2}(t)\| < 1$$
 $\|(x(t), y(t))\| < 1$ (def. of \mathbf{y}_{2})
$$\sqrt{x(t)^{2} + y(t)^{2}} < 1$$

$$x(t)^{2} + y(t)^{2} < 1$$

With the last inequality coming from the fact that $x(t)^2 + y(t)^2$ is nonnegative, and that the square of any number in the interval [0,1) is less than 1.

Problem 4

Problem: In each of the following, factor the matrix **A** into a product SAS^{-1} , with Λ a diagonal matrix:

$$\mathbf{a)} \ \mathbf{A} = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}$$

$$\mathbf{b)} \ \mathbf{A} = \begin{bmatrix} 5 & 6 \\ -1 & -2 \end{bmatrix}$$

Solution a): First we start be finding the eigenvalues of A, by finding the roots of its characteristic

polynomial:

$$0 = |\mathbf{A} - \lambda \mathbf{I}|$$

$$= \begin{vmatrix} 1 - \lambda & 1 \\ 0 & -\lambda \end{vmatrix}$$

$$= \lambda(\lambda - 1)$$

$$\Rightarrow \lambda = 0, 1$$

We now proceed to find a basis for both eigenspaces. We start with the eigenspace associated with the eigenvalue 0:

$$E_{0}(\mathbf{A}) = \text{Null}(\mathbf{A} - 0\mathbf{I}) \qquad (\text{def. of eigenspace})$$

$$= \text{Null}(\mathbf{A})$$

$$= \text{Null} \begin{bmatrix} 0 & 1 \\ 0 & -1 \end{bmatrix}$$

$$= \text{Null} \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \qquad (\text{rref})$$

$$= \text{Span} \left\{ \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right\} \qquad (x_{2} = 0, x_{1} \text{ free})$$

Now we do the same for the eigenspace associated with the eigenvalue 1:

$$E_1(\mathbf{A}) = \text{Null}(\mathbf{A} - \mathbf{I})$$
 (def. of eigenspace)

$$= \text{Null} \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}$$

$$= \text{Span} \left\{ \begin{bmatrix} 1 \\ -1 \end{bmatrix} \right\}$$
 $(x_2 = -x_1)$

We can now express the desired matrix S, whose columns are the eigenbasis of A:

$$\mathbf{S} = \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix}$$

Its inverse S^{-1} is given by:

$$\mathbf{S}^{-1} = \frac{1}{|\mathbf{S}|} \begin{bmatrix} S_{22} & -S_{12} \\ -S_{21} & S_{11} \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix}$$

And finally, Λ is given by the matrix whose diagonal entries are the cooresponding eigenvalues:

$$\mathbf{\Lambda} = \operatorname{diag} \begin{bmatrix} 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}$$

And so we can express our original matrix \mathbf{A} as the following eigendecomposition:

$$\mathbf{A} = \mathbf{S} \mathbf{\Lambda} \mathbf{S}^{-1} = \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix}$$

Solution b): Again, we start be finding the roots of **A**'s characteristic polynomial:

$$0 = |\mathbf{A} - \lambda \mathbf{I}|$$

$$= \begin{vmatrix} 5 - \lambda & 6 \\ -1 & -2 - \lambda \end{vmatrix}$$

$$= (5 - \lambda)(-2 - \lambda) + 6$$

$$= \lambda^2 - 3\lambda - 4 = (\lambda - 4)(\lambda + 1)$$

$$\implies \lambda = 4, -1$$

We now proceed to find a basis for both eigenspaces. We start with the eigenspace associated with the eigenvalue 4:

$$E_4(\mathbf{A}) = \text{Null}(\mathbf{A} - 4\mathbf{I}) \qquad (\text{def. of eigenspace})$$

$$= \text{Null} \begin{bmatrix} 1 & 6 \\ -1 & -6 \end{bmatrix}$$

$$= \text{Null} \begin{bmatrix} 1 & 6 \\ 0 & 0 \end{bmatrix} \qquad (\text{rref})$$

$$= \text{Span} \left\{ \begin{bmatrix} -6 \\ 1 \end{bmatrix} \right\} \qquad (x_1 = -6x_2)$$

Now we do the same for the eigenspace associated with the eigenvalue -1:

$$E_{-1}(\mathbf{A}) = \text{Null}(\mathbf{A} + \mathbf{I}) \qquad (\text{def. of eigenspace})$$

$$= \text{Null} \begin{bmatrix} 6 & 6 \\ -1 & -1 \end{bmatrix}$$

$$= \text{Null} \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} \qquad (\text{rref})$$

$$= \text{Span} \left\{ \begin{bmatrix} -1 \\ 1 \end{bmatrix} \right\} \qquad (x_1 = -x_2)$$

We can now express the desired matrix S, whose columns are the eigenbasis of A:

$$\mathbf{S} = \begin{bmatrix} -6 & -1 \\ 1 & 1 \end{bmatrix}$$

Its inverse S^{-1} is given by:

$$\mathbf{S}^{-1} = \frac{1}{|\mathbf{S}|} \begin{bmatrix} S_{22} & -S_{12} \\ -S_{21} & S_{11} \end{bmatrix} = -\frac{1}{5} \begin{bmatrix} 1 & 1 \\ -1 & -6 \end{bmatrix}$$

And finally, Λ is given by the matrix whose diagonal entries are the cooresponding eigenvalues:

$$\Lambda = \operatorname{diag} \begin{bmatrix} 4 & -1 \end{bmatrix} = \begin{bmatrix} 4 & 0 \\ 0 & -1 \end{bmatrix}$$

And so we can express our original matrix **A** as the following eigendecomposition:

$$\mathbf{A} = \mathbf{S} \mathbf{\Lambda} \mathbf{S}^{-1} = \begin{bmatrix} -6 & -1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 4 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} -\frac{1}{5} & -\frac{1}{5} \\ \frac{1}{5} & \frac{6}{5} \end{bmatrix}$$

Problem 5

Problem: For each matrix A in question 4, calculate A^7 .

Solution a): As we have already decomposed **A**, we can take advantage of the following property of diagonalizable matrices:

$$\mathbf{A}^{7} = (\mathbf{S}\boldsymbol{\Lambda}\mathbf{S}^{-1})^{7} \qquad (eigendecomposition)$$

$$= \mathbf{S}\boldsymbol{\Lambda}^{7}\mathbf{S}^{-1} \qquad (diagonalizable)$$

$$= \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}^{7} \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} 0^{7} & 0 \\ 0 & 1^{7} \end{bmatrix} \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix}$$

$$= \mathbf{S}\boldsymbol{\Lambda}\mathbf{S}^{-1} = \mathbf{A} \qquad (eigendecomposition)$$

$$= \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}$$

Solution b): Again, we have already decomposed **A** so we can take advantage of the following property of diagonalizable matrices:

$$\mathbf{A}^{7} = (\mathbf{S}\Lambda\mathbf{S}^{-1})^{7} \qquad (eigendecomposition)$$

$$= \mathbf{S}\Lambda^{7}\mathbf{S}^{-1} \qquad (diagonalizable)$$

$$= \begin{bmatrix} -6 & -1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 4 & 0 \\ 0 & -1 \end{bmatrix}^{7} \begin{bmatrix} -\frac{1}{5} & -\frac{1}{5} \\ \frac{1}{5} & \frac{6}{5} \end{bmatrix}$$

$$= \begin{bmatrix} -6 & -1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 4^{7} & 0 \\ 0 & -1^{7} \end{bmatrix} \begin{bmatrix} -\frac{1}{5} & -\frac{1}{5} \\ \frac{1}{5} & \frac{6}{5} \end{bmatrix}$$

$$= \begin{bmatrix} -6 & -1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 16384 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} -\frac{1}{5} & -\frac{1}{5} \\ \frac{1}{5} & \frac{6}{5} \end{bmatrix}$$

$$= \begin{bmatrix} 19661 & 19662 \\ -3277 & -3278 \end{bmatrix}$$

$$= \begin{bmatrix} 19661 & 19662 \\ -3277 & -3278 \end{bmatrix}$$

Problem 6

Problem: For each matrix **A** in question 4, calculate $e^{t\mathbf{A}}$.

Solution a): As we have already decomposed **A**, we can take advantage of the following property of exponential matrices:

$$\begin{split} e^{t\mathbf{A}} &= e^{t\mathbf{S}\mathbf{A}\mathbf{S}^{-1}} & \text{(eigendecomposition)} \\ &= \mathbf{S}e^{t\mathbf{A}}\mathbf{S}^{-1} & \text{(diagonalizable)} \\ &= \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix} \exp\left(\begin{bmatrix} 0 & 0 \\ 0 & t \end{bmatrix}\right) \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} e^0 & 0 \\ 0 & e^t \end{bmatrix} \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix} & \text{(diagonal matrix)} \\ &= \begin{bmatrix} e^t & e^t - 1 \\ 0 & 1 \end{bmatrix} \end{split}$$

Solution b): Again, we have already decomposed A so we can take advantage of the following property of exponential matrices:

$$\begin{split} e^{t\mathbf{A}} &= e^{t\mathbf{S}\mathbf{A}\mathbf{S}^{-1}} & \text{(eigendecomposition)} \\ &= \mathbf{S}e^{t\mathbf{A}}\mathbf{S}^{-1} & \text{(diagonalizable)} \\ &= \begin{bmatrix} -6 & -1 \\ 1 & 1 \end{bmatrix} \exp\left(\begin{bmatrix} 4t & 0 \\ 0 & -t \end{bmatrix}\right)\begin{bmatrix} -\frac{1}{5} & -\frac{1}{5} \\ \frac{1}{5} & \frac{6}{5} \end{bmatrix} \\ &= \frac{1}{5}\begin{bmatrix} -6 & -1 \\ 1 & 1 \end{bmatrix}\begin{bmatrix} e^{4t} & 0 \\ 0 & e^{-t} \end{bmatrix}\begin{bmatrix} -1 & -1 \\ 1 & 6 \end{bmatrix} & \text{(diagonal matrix)} \\ &= \frac{1}{5}\begin{bmatrix} 6e^{4t} - e^{-t} & 6e^{4t} - 6e^{-t} \\ -e^{4t} + e^{-t} & -e^{4t} + 6e^{-t} \end{bmatrix} \end{split}$$

Problem 7

Problem: Solve the following IVP:

$$\frac{d\mathbf{y}}{dt} = \underbrace{\begin{bmatrix} 4 & -2\\ 1 & 1 \end{bmatrix}}_{\mathbf{A}} \mathbf{y}, \ \mathbf{y}(0) = \begin{bmatrix} 1\\ 2 \end{bmatrix}$$

Solution: First we perform eigendecomposition on A, and to do this we first find A's eigenvalues:

$$0 = |\mathbf{A} - \lambda \mathbf{I}|$$

$$= \begin{vmatrix} 4 - \lambda & -2 \\ 1 & 1 - \lambda \end{vmatrix}$$

$$= (1 - \lambda)(4 - \lambda) + 2$$

$$= \lambda^2 - 5\lambda + 6$$

$$= (\lambda - 2)(\lambda - 3)$$

$$\implies \lambda = 2, 3$$

Now we find bases of both corresponding eigenspaces:

$$E_{2}(\mathbf{A}) = \text{Null}(\mathbf{A} - 2\mathbf{I}) \qquad \text{(def. of eigenspace)}$$

$$= \text{Null} \begin{bmatrix} 2 & -2 \\ 1 & -1 \end{bmatrix}$$

$$= \text{Null} \begin{bmatrix} 1 & -1 \\ 0 & 0 \end{bmatrix} \qquad \text{(rref)}$$

$$= \text{Span} \left\{ \begin{bmatrix} 2 \\ 1 \end{bmatrix} \right\} \qquad (x_{1} = x_{2})$$

$$E_{3}(\mathbf{A}) = \text{Null}(\mathbf{A} - 3\mathbf{I}) \qquad \text{(def. of eigenspace)}$$

$$= \text{Null} \begin{bmatrix} 1 & -2 \\ 1 & -2 \end{bmatrix}$$

$$= \text{Null} \begin{bmatrix} 1 & -2 \\ 0 & 0 \end{bmatrix} \qquad \text{(rref)}$$

$$= \text{Span} \left\{ \begin{bmatrix} 2 \\ 1 \end{bmatrix} \right\} \qquad (x_{1} = 2x_{2})$$

Letting $S = \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix}$, we now calculate \mathbf{S}^{-1} :

$$\mathbf{S}^{-1} = \frac{1}{|\mathbf{S}|} \begin{bmatrix} S_{22} & -S_{12} \\ -S_{21} & S_{11} \end{bmatrix}$$
$$= -\frac{1}{1-2} \begin{bmatrix} 1 & -2 \\ -1 & 1 \end{bmatrix}$$
$$= \begin{bmatrix} -1 & 2 \\ 1 & -1 \end{bmatrix}$$

And so we can express our original matrix \mathbf{A} as the following eigendecomposition:

$$\mathbf{A} = \mathbf{S} \mathbf{\Lambda} \mathbf{S}^{-1} = \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix} \begin{bmatrix} -1 & 2 \\ 1 & -1 \end{bmatrix}$$

We can now easily compute the matrix exponential $e^{t\mathbf{A}}$:

$$\begin{split} e^{t\mathbf{A}} &= e^{t\mathbf{S}\mathbf{A}\mathbf{S}^{-1}} & \text{(eigendecomposition)} \\ &= \mathbf{S}e^{t\mathbf{A}}\mathbf{S}^{-1} & \text{(diagonalizable)} \\ &= \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \exp\left(\begin{bmatrix} 2t & 0 \\ 0 & 3t \end{bmatrix}\right) \begin{bmatrix} -1 & 2 \\ 1 & -1 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} e^{2t} & 0 \\ 0 & e^{3t} \end{bmatrix} \begin{bmatrix} -1 & 2 \\ 1 & -1 \end{bmatrix} & \text{(diagonal matrix)} \\ &= \begin{bmatrix} 2e^{3t} - e^{2t} & -2e^{3t} + 2e^{2t} \\ e^{3t} - e^{2t} & -e^{3t} + 2e^{2t} \end{bmatrix} \end{split}$$

Finally, we can express the desired solution to the given IVP as the following matrix vector product:

$$\mathbf{y}(t) = e^{t\mathbf{A}}\mathbf{y}(0) = \begin{bmatrix} 2e^{3t} - e^{2t} & -2e^{3t} + 2e^{2t} \\ e^{3t} - e^{2t} & -e^{3t} + 2e^{2t} \end{bmatrix} \begin{bmatrix} 1 \\ 2 \end{bmatrix} = \begin{bmatrix} 3e^{2t} - 2e^{3t} \\ 3e^{2t} - e^{3t} \end{bmatrix}$$

Problem 8

Problem: Let **A** be a 2×2 matrix. Assume that the following vector functions:

$$\mathbf{y}_1(t) = \begin{bmatrix} e^t \\ -2e^t \end{bmatrix}, \quad \mathbf{y}_2(t) = \begin{bmatrix} 3e^{-2t} \\ e^{-2t} \end{bmatrix}$$

are solutions to the system $\frac{d\mathbf{y}}{dt} = \mathbf{A}\mathbf{y}$. Solve the following IVP:

$$\frac{d\mathbf{y}}{dt} = \mathbf{A}\mathbf{y}, \quad \mathbf{y}(0) = \begin{bmatrix} 1\\5 \end{bmatrix}$$

Solution: Recall that the solution set to a homogenous system of linear ODEs forms a vector space. Also note that the two given solutions $y_1(t)$ and $y_2(t)$ span the entirety of the solution set. We can verify this by noting that the Wronskian $W(y_1, y_2)(t) \neq 0$. This means that the desired solution y(t) is simply a linear combination of $y_1(t)$ and $y_2(t)$:

$$k_1 y_1(t) + k_2 y_2(t) = y(t)$$

$$k_1 y_1(0) + k_2 y_2(0) = y(0)$$

$$k_1 \begin{bmatrix} e^0 \\ -2e^0 \end{bmatrix} + k_2 \begin{bmatrix} 3e^0 \\ e^0 \end{bmatrix} = \begin{bmatrix} 1 \\ 5 \end{bmatrix}$$

$$k_1 \begin{bmatrix} 1 \\ -2 \end{bmatrix} + k_2 \begin{bmatrix} 3 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 5 \end{bmatrix}$$

We can express this system of linear equations as the following augmented matrix:

$$\begin{bmatrix} 1 & 3 & 1 \\ -2 & 1 & 5 \end{bmatrix} \xrightarrow{r_2 + 2r_1} \begin{bmatrix} 1 & 3 & 1 \\ 0 & 7 & 7 \end{bmatrix}$$
$$\xrightarrow{(1/7)r_2} \begin{bmatrix} 1 & 3 & 1 \\ 0 & 1 & 1 \end{bmatrix}$$
$$\xrightarrow{r_1 - 3r_2} \begin{bmatrix} 1 & 0 & -2 \\ 0 & 1 & 1 \end{bmatrix}$$

This leaves us with the constants $k_1 = -2$ and $k_2 = 1$. And so, our desired solution y(t) is given by:

$$y(t) = -2y_1(t) + y_2(t)$$

$$= -2 \begin{bmatrix} e^t \\ -2e^t \end{bmatrix} + \begin{bmatrix} 3e^{-2t} \\ e^{-2t} \end{bmatrix}$$

$$= \begin{bmatrix} -2e^t + 3e^{-2t} \\ 4e^t + e^{-2t} \end{bmatrix}$$
